What is 2019 Novel Coronavirus?

The 2019 Novel Coronavirus, or COVID-19, is a new respiratory virus first identified in Wuhan, Hubei Province, China. The initial reports of the outbreak suggested a link to a large seafood and animal market in Wuhan City; however, there is now evidence of broader person to person transmission. Cases are being reported from other parts of China and other countries, including the U.S.

The first case in the United States was announced on January 21, 2020. The first case of person-to-person transmission in the U.S. was reported on January 30, 2020, in a close contact to a confirmed case. More cases are likely to be identified in the United States and other countries in the coming days, and it is likely that person-to-person spread will continue to occur.

What is a novel coronavirus?

A novel coronavirus is a new strain in the coronavirus family that has not been previously identified. COVID-19 is not that same as the coronaviruses that commonly circulate among humans and cause mild illness, like the common cold. These are different viruses, and patients with COVID-19 will be evaluated and cared for differently than patients with common coronavirus diagnosis.

What is the source of COVID-19?

Public health officials and partners are working hard to identify the source of the COVID-19. Coronaviruses are a large family of viruses, some causing illness in people and others that circulate among animals, including camels, cats and bats. SARS, another coronavirus that emerged to infect people, came from cats, while MERS, another coronavirus that emerged to infect people, came from camels.

How does the virus spread?

Most often, spread from person-to-person happens among close contacts (about 6 feet). Person-to-person transmission is thought to occur mainly through respiratory droplets produced when an infected person coughs or sneezes, similar to how flu and other respiratory
germs spread. These droplets can land in the mouths or noses of people who are nearby or possibly be inhaled into the lungs.

It’s currently unclear if a person can get COVID-19 by touching a surface or object that has the virus on it and then touching their own mouth, nose, or possibly their eyes.

Typically, with most respiratory viruses, people are thought to be most contagious when they are most symptomatic (the sickest).

What are the symptoms of COVID-19?

Current symptoms reported for patients with COVID-19 have included mild to severe respiratory illness with fever, cough, and difficulty breathing. It can mimic flu symptoms including fatigue. The difference between the two is travel to China or close contact with someone who has been to China in the last 14 days.

How can I help protect myself?

There is currently no vaccine to prevent COVID-19. The best way to prevent infection is to avoid being exposed to this virus. However, as a reminder, the Mississippi State Department of Health (MSDH) recommends everyday preventive actions to help prevent the spread of respiratory viruses, including:

- Get a flu vaccine every year.
- Avoid close contact with people who are sick.
- Avoid touching your eyes, nose, and mouth with unwashed hands.
- Stay home when you are sick.
- Cover your cough or sneeze with a tissue, then throw the tissue in the trash.
- Clean and disinfect frequently touched objects and surfaces using a regular household cleaning spray or wipe.
- Wash your hands often with soap and water for at least 20 seconds, especially after going to the bathroom; before eating; and after blowing your nose, coughing, or sneezing.

Have there been cases of COVID-19 in Mississippi?

No, there are currently no confirmed cases in Mississippi and no one under investigation for possible infection in Mississippi.

Currently, the risk of infection in Mississippi is low, but the MSDH continues to actively monitor the situation. Transmission of the virus is currently dependent on exposure, through direct
travel to China within the past 14 days, or direct contact to someone with confirmed infection in the past 14 days.

What is Mississippi doing specifically to prepare for the spread of this virus?

The MSDH is working diligently with healthcare providers throughout the state to monitor the situation and has a plan in place to specifically monitor any travelers from China returning to Mississippi.

Additionally, any monitored individual who begins to show symptoms will be evaluated at an appropriate healthcare facility.

MSDH is working with all healthcare providers in the state to keep them aware of this changing situation and the latest recommendations as they become available.

Should I be tested for COVID-19?

If you develop a fever and symptoms of respiratory illness, such as cough or shortness of breath, 

**within 14 days after travel from China**, you should call ahead to a healthcare professional and mention your recent travel or close contact.

If you have had close contact with someone showing these symptoms who has recently traveled from this area, you should call ahead to a healthcare professional and mention your close contact and their recent travel.

Your healthcare provider will work directly with MSDH to determine if you need to be tested for COVID-19.

Am I at risk for novel coronavirus from a package or products shipping from China?

There is still a lot that is unknown about the newly emerged COVID-19 and how it spreads. In general, because these germs don’t live long on surfaces, there is likely very low risk of spread from products or packaging that are shipped over a period of days or weeks at ambient temperatures.

Coronaviruses are generally thought to be spread most often by respiratory droplets.

Currently there is no evidence to support transmission of COVID-19 associated with imported goods and there have not been any cases of COVID-19 in the United States associated with imported goods.
What about animals or animal products imported from China?

The Centers for Disease Control and Prevention (CDC) does not have any evidence to suggest that animals or animal products imported from China pose a risk for spreading COVID-19 in the United States. However, this is a rapidly evolving situation and information will be updated as it becomes available. Currently the strongest risk of transmission is respiratory droplets.
