SYNOPSIS OF VITAL STATISTICS MISSISSIPPI, 1968

INTRODUCTION

Description of Bulletin

The 1968 Vital Statistics Bulletin is the twenty-sixth annual report prepared by Statistical Services from information contained on records of live births, fetal deaths, deaths, marriages, and divorces collected by the office of Vital Records Registration. This synopsis provides certain explanations and definitions necessary for understanding the data presented and also summarizes the most noteworthy facts regarding the vital events of the year. Following the synopsis are ten tables (Numbers 1-10) containing statistics for 1968 and seven tables (Numbers 11-17) showing comparable data over a span of years, in most cases the entire period for which the information is available. The last section of the book contains a one-page summary table for each county and also for the state.

Definitions of Live Birth and Fetal Death

The definitions adopted by the Mississippi State Board of Health for use in Mississippi are those formulated by the World Health Organization and recommended by the National Center for Health Statistics. They are as follows:

Live birth - the complete expulsion or extraction from its mother of a product of human conception, irrespective of the duration of pregnancy, which, after such expulsion or extraction, breathes or shows any other evidence of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles, whether or not the umbilical cord has been cut or the placenta is attached.

Fetal death - death prior to the complete expulsion or extraction from its mother of a product of human conception, irrespective of the duration of pregnancy; the death is indicated by the fact that after such expulsion or extraction the fetus does not breathe or show any other evidence of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles.

Revised Certificate Forms and New Information Items

Mississippi, as well as most other states, began using revised certificates for live births, fetal deaths, and deaths in 1968. Each state decided upon the format of and items to be included on its own certificates, but all were either modeled after or the same as standard certificates designed by the National Center for Health Statistics in cooperation with the various states. The changes in 1968 were part of a periodic review and revision program undertaken to insure that these certificates adequately serve current legal and statistical needs of individuals and public health programs. The last revision in Mississippi prior to 1968 was in 1956.

Although the new death certificates contain only a relatively small amount of information not on the old certificates, the contents of the live birth and fetal death certificates were greatly expanded. The new information collected was considered to be of special value for planning public health activities directed toward

lowering Mississippi's excessively high infant mortality rate which is one of the state's most serious health problems.

Most of the new data items provide information never before available for Mississippi. However, considerable difficulty was experienced in collecting and tabulating this information. It was found that answers for new items were missing from many certificates; the proportion lacking answers for a certain item ranged from less than one percent of the live birth records to nearly 13 percent and from 6 to 22 percent of the fetal death records. In addition, there were numerous obvious inaccuracies. Because of these deficiencies, data compiled from the new items will have to be considered with some reservations.

Occurrence and Residence Allocation

Live births, fetal deaths, and deaths were classified by place of occurrence and by place of residence. Some of the tables contain both occurrence and residence figures, but most of the tables are based on residence data only, as these data are considered more suitable for studying public health problems. All figures given in this synopsis are residence counts unless otherwise stated.

Occurrence data were obtained from certificates filed in Mississippi at the place of the event. Residence data include transcripts of records of events that occurred in other states to Mississippi residents and exclude records filed in this state for non-residents. Residence assignment for live births and fetal deaths was determined by the usual residence of the mother. For deaths it was determined by the usual residence of decedent, except that deaths of inmates of institutions were reallocated to place of previous residence regardless of length of stay in the institution.

Table A provides information on vital events occurring out of the state to Mississippi residents and in Mississippi to nonresidents. The counts showed that 2,724 events to Mississippians were recorded in other places and that 2,423 records were filed in this state for events to nonresidents. States are listed on the table in order according to the total number of records involved. The largest number was exchanged with Tennessee, which is the only one of the states with an exchange of over 50 records from which Mississippi received more records than it sent. This state, together with the other three states which border on Mississippi (Alabama, Arkansas, and Louisiana), provided 90 percent of the transcripts received; these border states were also listed as the place of residence on 83 percent of the certificates filed in Mississippi for non-residents. However, although most of the vital record interchange was with neighboring states, Mississippi received transcripts from a total of 38 other states and the District of Columbia as well as one from out of the country and filed certificates for residents of 40 other states plus three for foreign residents.

Marriages were classified according to place of issuance of marriage license, place of occurrence of marriage, and place of residence of bride. However, the figures on brides who were Mississippi residents are incomplete since there is no exchange among the states of transcripts of marriage records for nonresidents and the out-of-state marriages of Mississippi brides could not be included. Divorces were classified only according to place where the decree was granted, as there is no information regarding place of residence on the record.

Table A. Transcripts of certificates filed in other places for Mississippi residents, by place of occurrence, and certificates filed in Mississippi for nonresidents, by place of residence, by type of certificate

Urban-Rural Classification

Incorporated towns with populations of 2,500 or more according to the 1960 census were considered as urban areas, and a total of 62 towns were included in this category. All other areas were classified as rural. These categories were used for live births, fetal deaths, and deaths only. Information on marriage records is inadequate for proper classification, and divorce records do not contain this item.

Population

The Mississippi State Board of Health does not make population estimates but uses those prepared by the Division of Sociology and Anthropology of Mississippi State University. However, these estimates are based in part on live birth and death figures provided by the State Board of Health for this purpose.

Rates

Rates and ratios were calculated from residence data on live births, fetal deaths, and deaths. Estimated populations for the state and counties by race were used to prepare rates for live births, total deaths, and deaths from specific causes (except maternal and certain causes of mortality in early infancy). Although compilation of rates by age and sex and for cities is desirable, this could not be done because of the lack of population data for these categories. Figures on live births were used to calculate fetal death ratios and rates for maternal deaths, infant deaths, neonatal deaths, and deaths from certain causes of mortality in early infancy, as they approximate the groups at risk more closely than do general population figures.

The base for each type of rate used in this bulletin is given in the footnote on page 59.

Classification of Cause of Death

Development of a system for classifying diseases began in Europe in the 1700's. By the end of the nineteenth century a standard classification of causes of death was being used in several countries and had been adopted for use in the United States. This classification has been revised approximately every ten years since 1900 in order to keep pace with new knowledge in the field of medicine. The latest version, Eighth Revision International Classification of Diseases, Adapted for Use in the United States, went into effect in Mississippi and a majority of the other states in 1968.

AND THE PARTY OF T

A list of the international classification numbers and group titles for the new revision is presented here to show the organization of the system.

000-136 Infective and parasitic diseases

140-239 Neoplasms

240-279 Endocrine, nutritional, and metabolic diseases

280-289 Diseases of the blood and blood-forming organs

290-315 Mental disorders

320-389 Diseases of the nervous system and sense organs

390-458 Diseases of the circulatory system

460-519 Diseases of the respiratory system

520-577 Diseases of the digestive system

580-629 Diseases of the genitourinary system

630-678 Complications of pregnancy, childbirth, and the puerperium

680-709 Diseases of the skin and subcutaneous tissue

710-738 Diseases of the musculoskeletal system and connective tissue

740-759 Congenital anomalies

760-779 Certain causes of mortality in early infancy

780-796 Symptoms and ill-defined conditions

800-999 Accidents, poisonings, and violence

On certificates with more than one cause entered, only that indicated as the underlying cause was classified, but the system can be used for studying all conditions listed on death certificates.

Although standard classification enables comparison of statistics from one country or state with those of another country or state regardless of language or terminology differences, the periodic revisions which have taken place in the past have resulted in an unavoidable lack of comparability over the years for some causes of death. The greatest change was in the Sixth Revision in 1949, and only minor changes were incorporated in the Seventh Revision which went into use in 1958. Differences between the Seventh and Eighth Revisions have not been fully analyzed yet; but it appears that, although they are of more consequence than those between the Sixth and Seventh Revisions, there was a relatively small number of causes with major changes. Because of these revisions, comparisons of data over a period of years should be made with caution. However, the National Center for Health Statistics has prepared and published comparability ratios which show the effect revisions have had on each cause and which may be used to adjust figures for the purpose of analyzing trends.

LIVE BIRTHS (See Tables 2, 3, 11)

Trend

number of live births, as did the country as a whole. The total count of 45,719 births to Mississippi residents was 23 percent lower than the figure of 59,523 reported for 1961, the last year before the decrease began. However, the rate of decline slowed considerably after reaching a peak of 9.7 percent in 1965 and in 1968 amounted to only 1.9 percent. In 1968 the live birth rate was 19.4 per 1,000 population, but it should be noted that population estimates made this long after the decennial census are subject to sizeable inaccuracies which would, of course, affect any figures based on them. This rate was the second lowest on record, exceeding only that for 1917, and the number of births was the smallest since 1933.

Race

Counts by race showed a difference of only 105 between the figure of 22,807 for whites and that of 22,912 for nonwhites. In every year since 1924 the nonwhite total has been the larger; but if the trend continues in 1969 as it has in recent years, the reverse will be true. Although the numbers for the two groups were nearly the same, there was still a large gap between the rates; for whites the rate was only 15.7 per 1,000 population, but for nonwhites it was 25.4. The figure for whites was the lowest ever calculated, and that for nonwhites was the smallest since 1935.

County

Among both races there was marked variation in the county rates. The range for whites was from 6.1 in Jefferson County to 21.0 in Jackson County; for nonwhites the lowest was 11.7 in Tishomingo County and the highest, 39.3 in Greene County. However, the previously mentioned difficulties with population estimates could be responsible for some of this variation.

<u>Urban-Rural Variation</u>

Children born to urban residents numbered 18,879 and to rural residents 26,840. Comparison of counts by place of occurrence and place of residence showed that although only 41 percent of the births were to urban residents, 73 percent occurred in urban places, indicating that many mothers from rural areas went to towns and cities for delivery. This figure was estimated to be over 8,500 for whites and over 5,500 for nonwhites.

Natural Increase (Excess of Birth Rate over Death Rate)

The continued decline in the birth rate coupled with a rise in the death rate produced the lowest rate of natural increase since 1929. The actual excess of the birth rate over the death rate was 9.2 per 1,000 population in 1968 and less than half the rate of 19.1 only 11 years earlier in 1957. In number of people the natural increase amounted to 21,733 during 1968. The rate of gain among the nonwhite population was more than twice that for the whites, 13.8 in comparison with 6.4, but this was the lowest rate the nonwhites had experienced since 1936. However, the rate for whites was the smallest on record for this race. Deaths outnumbered births among the white population in 13 counties (Amite, Benton, Carroll, Choctaw, Franklin, Holmes, Jefferson, Kemper, Newton, Tallahatchie, Webster, Wilkinson, and Yalobusha), and the two figures were equal in Noxubee County. There was also one county, Tishomingo, where the non-whites experienced one more death than birth; however, both figures were small. Jackson

County had the highest rate of natural increase noted for whites and Smith County the highest for nonwhites.

Attendant

Information presented in Table Bl shows that 84 percent of the live births to residents of Mississippi took place in hospitals or clinics which provide in-patient care. One percent were delivered by physicians in locations other than a hospital or clinic, and the remaining 15 percent had no medical attendant. The difference by race in care at delivery was quite pronounced. All but a fraction of one percent of the white mothers were delivered in hospitals and clinics but 6,643 or 29 percent of the non-white mothers had no medical care at delivery.

Table Bl. Live births and percentage distribution, by attendant and race

		Number			Percent			
Attendant	Total	White	Non- white	Total	White	Non- white		
<u>Total</u>	45,719	22,807	22,912	100.0	100.0	100.0		
Hospital or clinic Physician, other place	38,525 482	22,704 34	15,821 448	84.3	99.5 0.1	69.0		
Midwife Other	6,621	54 15	6,567 76	14.5 0.2	0.2	28.7 0.3		

Impressive gains have been made in the last twenty years in obtaining hospital care for delivery with the proportion hospitalized almost doubling (refer to Table B2). The increase from 14 percent in 1948 to 69 percent in 1968 for the nonwhites has been even more spectacular. However, Mississippi still compares unfavorably with the nation in this regard, as the national figure for nonwhite deliveries in hospitals in 1968 was 94 percent.

Table B2. Percentage of live births in hospitals or clinics, by year and race, 1948, 1958, 1964-1968

Year	Total	White	Non- white
1948	42.8	77.9	13.6
1958	70.4	98.6	47.0
1964	76.0	99.4 99.4	56.1
1965 1966	77.3 79.3	99.4	58.8 61.4
1967 1 96 8	82.1 84.3	99.5 99.5	65.5 69.0

Month

The seasonal variation in births is readily apparent in Table B3. These figures show that there were considerably fewer births in the first six months of the year than in the second half and that the lowest level was reached in the spring months of March, April, and May. August was the month with the largest total number and the highest daily average, but December was a close second.

Table B3	3. Live	births	and	average	per	day,	by	month
----------	---------	--------	-----	---------	-----	------	----	-------

Month	Births	Average per Day	Month	Births	Average per Day
Total	45,719	125			
January	3,826	123	July	4,045	130
February	3,541	122	August	4,234	136
March	3,548	114	September	3,931	131
April	3,356	112	October	3,905	126
May	3,572	115	November	3,931	131
June	3,668	122	December	4,162	134

Age of Mother

Eighty percent of the babies born in 1968 were born to mothers between the ages of 15 and 29. The greatest concentration was in the ages 20-24, as shown in Table B4, with this group accounting for 36 percent of the total births. Age distributions of white and nonwhite mothers were considerably different; there were relatively fewer nonwhites than whites 20-29 years of age and higher proportions of nonwhites in the younger and older groups. As a result of the excess of nonwhite mothers under age 20, their median age (22.8 years) was less than that of 23.7 years for white mothers. The youngest Mississippi mother in 1968 was only 10 years old there were two others who were only 11 years of age. There were also 13 who were 12 years old and 60 whose age was 13. Although the total number of births continued to decline in 1968, the number to white mother ages 20-29 and to nonwhite mothers under 20 increased. It is likely that at least part of this rise is due to the fact that the unusually large number of babies born in the years immediately after World War II have now reached the age to have children themselves.

Table B4. Live births and percentage distribution, by age of mother and race

		Number			Percent

^{*} Less than 0.06 percent.

Education of Parents (New information)

Information on education of mother and father was included on Mississippi certificates and those of many other states beginning in 1968. The highest grade of school completed by each parent is considered to be one of the best indicators of socio-economic status that can be obtained and is much simpler to define and tabulate than the information previously collected regarding occupation. Education level of the parents is of particular relevance in the consideration of type of prenatal care sought by and provided for mothers, care the infant receives after birth, and family planning.

The first data available for Mississippi on this subject are summarized in Table B5. Median years of school completed by each parent are shown along with numerical and percentage distributions according to total years completed. Since no information about fathers of illegitimate children is collected, illegitimate births were excluded from the figures on education of the father. On the right hand side of the table, percentages are cumulated downward so that the figure opposite each level of education represents the sum of those who did not advance beyond the highest year in that level. These figures show that 48 percent of the fathers and 54 percent of the mothers had not graduated from high school. Although the number who had not completed even one year of school was extremely small, those who had gone no farther than the sixth grade numbered in the thousands and nearly one-third of both fathers and mothers had not gone beyond the ninth grade. Tabulations by race revealed that nonwhite parents had significantly less education than white parents. Differences in age distribution probably are partly responsible for this; for example, nonwhite mothers under the age of 18 made up 14 percent of the total but only 6 percent of the white mothers were this young. There was a difference of almost three years in the median years of school completed by white and nonwhite fathers and a difference of 2.2 years for the mothers. Almost three-fourths of the nonwhite fathers and mothers had not completed high school.

Table B5. Live births and percentage distribution, by years of school completed by father and mother and race

^{*} Calculations exclude births to parents with education unknown; calculations for fathers also exclude illegitimate births.

Data on education of parents and legitimacy were combined to produce a more complete picture of the socio-economic status into which Mississippi children were born. These figures showed that only 53 percent of the white and 10 percent of the nonwhite children were legitimate and also born into families in which both parents had at least a high school education, two conditions that might be considered as minimal for normal family life and adequate support of a family.

Legitimacy

Information recorded on birth certificates showed that 8,577 or 18.8 percent of the children born to Mississippi mothers in 1968 were illegitimate. For white mothers the count was 686 and the percentage 3.0; corresponding figures for nonwhites were 7,891 and 34.4 percent. Among both races the trend has been upward for many years - since 1957 for the whites and since 1949 for the nonwhites. The percentage for whites, though small, has tripled in that time and that for nonwhites has more than doubled.

The ratio of illegitimate to total births was highest among mothers under 20 years of age which is, of course, the population group with the largest proportion of unmarried women. It was found that 39 percent of the births to mothers in this age group were illegitimate, and that the proportion has risen steadily in recent years. In other groups the proportion ranged from 9 to 15 percent.

Special new tabulations on legitimacy revealed that the mothers of 22 percent of the white illegitimate children and 52 percent of the nonwhite illegitimate children had had previous deliveries. However, it is not known how many of the previous births were also illegitimate.

Total-Birth Order and Average Number of Births per Mother (New information)

Although information regarding number of previous deliveries to the mother had been on birth certificates prior to 1968, it had not been tabulated in Mississippi since 1954 because of doubts concerning the validity of the entries. It was evident in compiling this information for 1968 that the accuracy of reporting is still questionable, and, therefore, the figures will have to be accepted with reservations. However, it is believed that these items contain fewer errors than some of the new items added to the certificate in 1968. Also, the tabulations showed that the proportion of records with these facts not stated was smaller than the proportions of certificates with newly added items not answered.

In 1968, nearly a third of the live births were the first delivery to that mother; the figures in Table B6 show that these first births numbered 14,868. An additional 22 percent were second in total-birth order; thus 54 percent were included among mothers' first two deliveries. (Total-birth order is based on live births plus all fetal deaths regardless of length of gestation.) As birth order increased the number of births steadily declined. However, there were 10,098 births of the fifth or higher orders (22 percent of the total), and 2,272 or 5 percent were of the tenth or higher orders. Twenty mothers, all nonwhite, reported having 20 or more deliveries, with 23 the largest total number. Comparisons by race revealed that relatively more of the white than of the nonwhite births were among the first through third total-birth orders, that the percentages were approximately the same for fourth births, and that proportionately fewer of the whites were of fifth or higher orders (only 11 percent as compared with 33 percent of the nonwhites). Nine percent or 1 out of every 11 nonwhite births was tenth or higher in delivery order.

As shown in Table B6, the median age of mothers at first delivery was 19.9 years. For each birth order nonwhite mothers were younger than white mothers; at first delivery the difference in the median ages was 2.1 years, and for the second through seventh orders there were differences of three to four years. Closer spacing of children among the nonwhites than among the whites is indicated by the fact that there was a difference of 7.4 years between the median ages of white mothers having their first child and those having their fourth delivery in comparison with only 5.5 years for nonwhite mothers.

^{*} Includes all live births plus all fetal deaths regardless of length of gestation.

Table B7 provides additional information on age of and deliveries to mothers, but shows number of deliveries per mother by age group rather than ages of mothers by birth order. According to these figures, mothers of children born in 1968 had experienced an average of 3.2 deliveries (including the child born in 1968 and all fetal deaths). The average number increased with the age of the mother, of course, reaching 9.2 at ages 40-44 and 11.3 at 45 years and over. The overall average for white mothers was 2.4 and for nonwhites, 4.1. For all age groups 15 years of age and over the average for nonwhites was higher than that for whites, but for mothers 15-19 the difference between the races was not extreme. However, the size of disparity increased steadily with age up to the age of 45 denoting an accumulation of excess fertility among the nonwhites.

Table B7. Average number of total births and living children per mother, (for mothers who had a live birth in 1968), by age of mother and race

45 and over	11.3	7.3	12.1	10.0	6.6	10.7	

^{*} Includes the child born in 1968, all other live births, and all fetal deaths regardless of length of gestation.

^{**} Includes the child born in 1968 and all other children still living at the time of that delivery.

Table B7 also contains data on average number of living children per mother which is an indication of family size. (Living children include the child born in 1968 and all other children still living at the time of that delivery.) These calculations disclosed that the average was 2.2 for white mothers and 3.7 or 68 percent higher for nonwhites.

Last Prior Delivery (New information)

Specific information regarding the dates of last live birth and last fetal death was collected in Mississippi for the first time in 1968. As was true for other new items added in 1968, many certificates had entries that were obviously incorrect or had no entry; and, therefore, the reliability of the figures presented here is somewhat questionable. The two dates were used to determine the outcome of the last prior delivery and calculate the interval between it and the child born in 1968. Researchers have found the health of both the mother and the child to be adversely correlated with spacing of pregnancies at intervals of less than two years and with a history of previous fetal deaths.

^{*} Excludes those with outcome of last delivery unknown.

^{**} Calculated from ungrouped data.

Information in Table B8 relating to mothers who had had previous pregnancies shows that the median interval since the last delivery was 26.0 months. However, it was noted from more detailed figures than are given in the table that more births occurred during the second year after a preceding delivery than in any other twelvemonth period. This was true for both race groups and whether the preceding delivery was a live birth or a fetal death. Almost 10 percent of the births that were from second or later pregnancies had been preceded by a fetal death at the last pregnancy, and the percentage was higher for whites (12) than for nonwhites (7). Further study of spacing in relation to race and outcome of last prior delivery revealed that spacing patterns for white mothers delivering after a fetal death and nonwhite mothers delivering after either a live birth or a fetal death were similar but that white mothers who delivered after a live birth had a quite different pattern and their median interval was 35.1 months in comparison with 19.1, 22.1, and 16.9 months respectively for the other mothers.

Prenatal Care (New information)

The month of pregnancy in which prenatal care began and the number of prenatal visits to a physician or clinic were among the new items added to birth certificates in 1968. Since a number of certificates had no answers in one or both of these items and on some records the entries were obviously wrong, the validity of the data obtained from these items is subject to question. It was reported that 1,202 or 2.6 percent of the mothers had no prenatal care; and, as was anticipated, proportionately more of the nonwhites (4.4 percent) than of the whites (0.8 percent) lacked care. In addition there were also 2,026 mothers whose records did not reveal whether they had any prenatal care.

Analysis of the time prenatal care began showed that 56 percent of the mothers went to a physician or clinic during the first three months of pregnancy, 25 percent waited until the second trimester to begin care, and 10 percent did not receive any care until the third trimester(see Table B9). Although the difference between the proportions of white and nonwhite mothers who received some prenatal care was not large, there was a sharp contrast between the two races in how early in pregnancy care began. Among whites 74 percent had care in the first trimester, but only about half that proportion, 38 percent, of the nonwhites sought medical advice in the first three months.

Information presented in Table B9 relating to number of prenatal visits shows that one-third of the mothers had 6-10 visits and that approximately the same proportion (29 percent) had under 6 visits as had more than 10. The average number per mother who received care was 8.4. Nonwhite mothers averaged only a little over half as many visits (5.9) as the white mothers (10.8), and this correlates with the fact that the nonwhite mothers did not begin prenatal care as early in pregnancy as the white mothers. An additional illustration of the disparity between the two race groups is that only 9 percent of the white mothers had under 6 visits and 48 percent had more than 10, whereas the reverse was true for nonwhites with 48 percent having less than 6 visits and only 9 percent having more than 10.

Complications during Pregnancy and Labor (New information)

The year 1968 was the first in which an attempt was made to have medical information about complications during pregnancy and labor recorded on birth certificates. However, the results were disappointing. For 13 percent or 1 out of every 8 births it was unknown whether the mother had any complications, and much of the information which was provided on the remainder of the records was entered in such a way that its proper classification was extremely doubtful. It is likely that in many of the instances in which there was no information given no complications occurred, but this could not be taken for granted.

Complications were reported on 4,966 records or about 11 percent of the total (see Table B10), but this should be considered as a minimum figure. In addition to the previously mentioned difficulties with the records, there were numerous conditions such as the common cold, pleurisy, virus, itch, blackout, emotional upset, back pain, dehydration, numbness, etc. which were not counted because they were considered insignificant or too vague for classification. However, since no clear definition of what is to be considered as a complication has been established, deciding what to accept and what to reject was a serious problem which was never satisfactorily solved. Finally, on numerous records it was indicated that a cesarean section or other procedure was done, but the complication which necessitated it was not recorded. The proportion of white mothers

with at least one complication was slightly higher than that for nonwhite mothers, 11.7 percent in comparison with 10.0 percent. This difference, however, may be merely a reflection of a difference in number of conditions diagnosed as the white mothers received more medical care during pregnancy and labor.

Table B10. Live births and percentage distribution, by whether mother had complications during pregnancy and labor, category of complication, and race

		Number			Percent

ed to pregnancy Of labor	(1,171) (2,258)	(614) (1,303)	(557) (955)	(2.6) (4.9)	(2.7) (5.7)	(2.4) (4.2)
Unknown whether any complications	5,742	2,853)	2,889	12.6	12.5	12.6

Table B10 also provides information on number and percentage of records showing complications in each of the three major categories. (These figures add up to more than the total number with complications as some mothers had complications in more than one category.) About 1 out of every 20 or 5 percent of the mothers were known to have had complications directly related to this pregnancy and the same proportion had complications during labor. In addition, 2.6 percent had complications during pregnancy that did not arise from the pregnancy itself.

Data presented in Table Bll pertain to the number of specific complications listed rather than the number of mothers with complications. Some of these complications such as hemorrhages and premature rupture of membranes can occur either during pregnancy or at the time of labor. Others such as hypertension and anemia can be either related to pregnancy or not related to pregnancy depending upon whether they arose during the pregnancy or existed as a chronic condition prior to pregnancy. Determination of the proper category was a matter of guesswork in many such cases. Sections of the Eighth Revision of the International Classification of Diseases, Adapted for Use in the United States were used for specific classification of complications within the three major categories: codes 630-639 for those related to pregnancy, codes 760 and 761 for those not related to pregnancy, and codes 651-662 for those of labor. However, the index for the Eighth Revision was not available until records for eleven months of the year had already been processed, and it was found after the index was received that a number of conditions had been incorrectly classified during the first eleven months.

All of the complications with specific codes which appeared on as many as 100 certificates are shown in Table Bl1. Toxemias of pregnancy were listed more frequently than any other complication in any of the three major categories; they appeared on 1,179 records and accounted for 19 percent of the total reported. This was the leading complication only among nonwhite mothers, however, as malpresentation of the fetus at the time of delivery was listed more frequently than any other among white mothers and ranked

second in the total group with 773 cases reported. The third-ranking condition was hemorrhage with a total of 652 either during pregnancy or during labor, and this also was listed more often for whites than for nonwhites.

Length of Gestation and Birth Weight

For a number of years information about length of gestation and birth weight has been collected and tabulated in Mississippi. The item on birth weight was added to the certificate in 1949 and has remained unchanged since that time. Information relating to length of gestation has been collected since 1929, but the form in which it has been requested has changed several times. In 1949 this item was revised to show number of weeks of gestation. However, the method of determining the number of weeks was left to the attendant, and it was apparent that in many instances no attempt was made to calculate the correct period. The length of gestation for the vast majority of births was reported as 40 weeks. Among the remainder there was concentration in the even-numbered weeks.

Since the method of collecting gestation information used since 1949 yielded unsatisfactory results, a different method was initiated in Mississippi and most other states

with the certificate revision of 1968. The attendant was requested to give the exact date of the mother's last menstrual period (LMP) prior to delivery so that the number of completed weeks of gestation could be accurately calculated by determining the interval between the LMP and the date of delivery. Because the LMP is a date, often unnoted at the time, that must be recalled by the mother at some later time (in many instances several months later), the accuracy of this item is probably more questionable than that of any other on the birth certificate. Despite this difficulty, however, the figures obtained by this method are superior to those previously collected.

Table B12 reveals the sharp contrast between the two methods. In 1967, the last year in which the attendant was asked to state the number of weeks, nearly 86 percent of the births were recorded with a gestation period of 40 weeks, whereas in 1968, from calculations using the LMP, only 18 percent were found to be at 40 weeks. In addition, there were substantial differences in the proportions of premature deliveries (5 percent under 37 weeks in 1967 and 17 percent in 1968) and of deliveries after more than 40 weeks of gestation (2 percent in 1967 and 21 percent in 1968). Even greater differences were noted in the incidence of prematurity among nonwhites and pregnancies of more than 40 weeks among the whites.

Table B12. Percentage distribution of live births, by completed weeks of gestation and race, 1967 and 1968

The major reason for collecting data on gestation period and birth weight is to study the problem of babies who are not mature when born. The term "premature" is frequently used to indicate those for whom a lack of maturity is indicated by a gestation period of less than 37 weeks, and the term "immature" is used to indicate a birth weight of 5 1/2 pounds (2,500 grams) or less. The two conditions are, of course, correlated; but, as the figures in Table B13 make clear, the correlation was far from perfect. A total of 2,428 (5.3 percent) of the infants born alive in 1968 met both criteria for lack of maturity. An additional 2,065 were classified as immature but not premature, bringing the total proportion that were immature up to 9.8 percent. There were 5,157 others who were premature but not immature, raising the incidence

^{*} Less than 0.06 percent.

of prematurity to 16.6 percent. The total number of babies affected by either a low birth weight and/or a significantly shortened gestation period was 9,650 or 21.1 percent. Regardless of what measurement of lack of maturity was used, the percentage was higher for nonwhites than for whites. The difference between the races was greater when measured by gestation period, however, than when measured by weight.

		Number			Percent	
Maturity*	Total	White	Non- white	Total	White	Non- white
Total	45,719	22,807	22,912	100.0	100.0	100.0
Immature only** Premature only** Both immature and premature	2,065 5,157 2,428	735 1,547 913	1,330 3,610 1,515	4.5 11.3 5.3	3.2 6.8 4.0	5.8 15.8 6.6

Neither immature nor premature**	36,069	19,612	16,457	78. 9	86.0	71.8

Table B13. Live births and percentage distribution, by maturity and race

Sex

Counts by sex showed 23,428 males and 22,291 females and these figures yielded a sex ratio of 1,051 males per 1,000 females; comparison of the ratios for the past 25 years revealed that they have varied from 1,024 to 1,052. In all years for which sex ratios have been calculated that for the whites was higher than that for nonwhites, and in 1968 the figures were 1,077 and 1,026 respectively.

Plurality (See Plurality in Fetal Death section also)

Live births from plural deliveries numbered 1,127 and comprised 2.5 percent of the total. Figures by race were 2.0 percent for whites and 3.0 percent for nonwhites. Tabulation by age of mother revealed that the proportion of plural births was the same for the two groups under age 20, increased steadily from ages 15-19 through ages 35-39, and then declined. The highest percentage was 5.0 among mothers 35-39 years old and the lowest, 1.6 for the groups under age 20. At all ages except 40-44 the proportion was greater among nonwhite mothers than among whites with the largest difference in the peak interval (ages 35-39) where the figure for nonwhites was more than twice as high as that for whites.

^{*} Immature - birth weight 5 1/2 pounds (2,500 grams) or less; premature - gestation less than 37 weeks.

^{**} Births classified as immature only or as premature only include some for which the other measurement was unknown. Those classified as neither immature nor premature include some for which one or both measurements were unknown.

Further analysis showed extremely high proportions of babies with low birth weight and of deliveries before term among the plural deliveries. Seven times as many of the plural births as of the single births weighed 5 1/2 pounds or less (56 percent in comparison with 8 percent), and about three times as many had a gestation period of less than 37 weeks (46 percent in comparison with 15 percent). Differences between single and plural births in birth weight and in weeks of gestation were greater for whites than for nonwhites.

Birth Injuries and Congenital Malformations (New information)

A majority of the states had sections for birth injuries and congenital malformations on their birth certificates in 1968. Many already had one or both items on their records prior to 1968 and others, including Mississippi, added them in that year as a result of the incorporation of these two items into the standard certificate which serves as a model. Most of the remaining states had only a section for congenital malformations. As was true for the new items on complications during pregnancy and labor, there were large numbers of certificates with no entry in the sections relating to the condition of the baby - 13 percent or about 1 out of every 8 (see Table B14). Although it is likely that in many of these instances there was nothing wrong with the child, this was not known to be so and could not be assumed. Malformations and/or injuries were reported on 522 or 1.1 percent of the certificates, with 7 children having both an injury and a malformation; and on nearly 86 percent it was stated that there were none. Slightly more of the whites than of the nonwhites had malformations or injuries listed, but this could be the result of better diagnosis and reporting for white children since over 99 percent were born in hospitals or clinics.

Table B14. Live births and percentage distribution, by whether child had any birth injuries or congenital malformations, whether injury or malformation, and race

		Number		Percent

Unknown whether injury or					1	I	
malformation	6,076	2,841	3,235	13.3	12.4	14.1	

Birth injuries were mentioned on only 89 records which is 0.2 percent of the total. It is probable that there were others which were not recorded because of the fear of blame or even legal action against the attendant, but the degree of underreporting is not known. No spinal cord injuries and only 10 brain injuries were listed; 36 injuries to bone and nerve were reported and 42 in all other categories. One case of multiple injuries was recorded which involved the brain and another site.

Although more congenital malformations than birth injuries were reported, underreporting is also considered to be a problem in analyzing the occurrence of congenital malformations because of several reasons. Some types of malformations, especially of internal organs, are not apparent at the time of birth and others, although recognizable by trained physicians, might not be noted by midwives, who delivered 29 percent of the nonwhite babies in 1968. Undoubtedly there were also instances where a diagnosed malformation was not recorded for fear of stigmatizing a child. Table B15 shows that a total of 518 were reported. (The actual total reported probably was slightly higher as there was room on the punch card used for tabulating purposes for only three per child and a few children may have had more than three.) However, only 440 children were affected as 54 had two malformations each and 12 had more than two each. Among body sites the musculoskeletal system ranked first, partly because of ease of recognition; 94 of the 207 reported were polydactyly (extra fingers and toes) and 43 were club foot. The digestive system ranked second; and, again, this was probably due at least in part to the fact that it included a sizeable number of an easily recognized condition - 56 cases of cleft palate and/or cleft lip among the total of 100 for this system. Other systems for which 50 or more malformations were reported were the nervous system (55 cases) and genital organs (54 cases).

FETAL DEATHS (See Table 4)

Reporting and Reliability

In Mississippi the State Board of Health has required the registration of all fetal deaths, regardless of the length of gestation, since 1952. (The reporting requirement prior to that year was for stillbirths of 20 or more weeks of gestation.) However, it is obvious from the results obtained that registration of early fetal deaths as well as those that occur after 20 or more weeks gestation is far less complete than that for live births or deaths. The degree of underreporting is not known but is thought to be significant; and, therefore, the information presented herein regarding fetal deaths may not be reliable.

Trend and Race

A total of 2,373 such events were recorded in Mississippi in 1968, and the count

for residents of the state was 2,322. Although these figures were only slightly larger than those for 1966 and 1967 and considerably less than those for the early 1960's, the fetal death ratio of 50.8 per 1,000 live births was the highest recorded in the seventeen years of all-inclusive registration. Only among the whites was an increase noted, however; both the number and ratio for nonwhites went down. These opposite changes brought the ratios for the two groups closer together; but, as usual, that for the nonwhites was higher, 52.5 in comparison with 49.1 for whites.

County

County ratios showed extreme variation. For the white population they ranged from zero in three counties to 142.8 in Issaquena County, and for nonwhites they went from zero in four counties to 285.7 in Tishomingo. Differences such as these, even though partly due to variations in the age distribution of the population and other factors, are probably in large measure the result of differences in reporting. If it is assumed that the high ratios in counties where the number of live births and fetal deaths is large enough to provide a reliable calculation represent complete reporting, it can be estimated that at least ten percent of all deliveries terminate in fetal deaths; special studies done in other places have estimated the true incidence in excess of twenty percent.

Attendant

Nearly 90 percent of the fetal deaths to Mississippi residents in 1968 were delivered in hospitals or clinics (refer to Table Cl). Physicians attended 2 percent in homes and other places, and for 192 or 8 percent there was only a midwife or other nonmedical person in attendance. Even though just 2 white mothers did not receive medical attention during delivery, 190 nonwhite mothers (16 percent of the total) did not have a physician in attendance. Relatively more of the nonwhite mothers, however, were hospitalized at delivery of a fetal death than at delivery of a live birth (81 percent vs. 69 percent), but this is to be expected when it is considered that prematurity and complications are commonly associated with death of the fetus.

Table C1. Fetal deaths and percentage distribution, by attendant and race

	Number			Percent		
Attendant	Total	White	Non- white	Total	White	Non- white
<u>Total</u>	2,322	1,119	1,203	100.0	100.0	100.0
Hospital or clinic Physician, other place Midwife Other	2,078 52 183 9	1,101 16 2 0	977 36 181 9	89.5 2.2 7.9 0.4	98.4 1.4 0.2	81.2 3.0 15.0 0.7

Advances in securing hospital care when a fetal death occurs are evident from the data in Table C2. Significant gains were made by both race groups in the last ten years and the gap between the two narrowed considerably (from 32 percentage points to 17).

Table C2. Percentage of fetal deaths delivered in hospitals or clinics, by year and race, 1958, 1964-1968

Year	Total	White	Non- white
1958	69.0	88.8	56.8
1964	79.7	92.0	70.1
1965 1966	79.4	95.8 97.5	67.5 71.9
1967 1968	86.2 89.5	97.7 98.4	76.8 81.2

Age of Mother

The fetal death ratio (number of fetal deaths per 1,000 live births) was lowest for mothers 15-19 years of age and rose steadily with increasing age as shown in Table C3. Mothers 40-44 years old had the highest ratio calculated which was 120.2, or more than three times greater than the low figure for those of ages 15-19. Among the very young mothers (ages 10-14) the ratio was higher than for any others under the age of 30 but less than for any 30 and over. Oddly enough, although most of the ratios for nonwhites were higher than those for whites, the lowest ratio of all was that for nonwhite mothers 15-19 years old.

Table C3. Fetal deaths and fetal death ratios, by age of mother and race

		Number			Ratio*

^{*} Fetal deaths per 1,000 live births to mothers in specific agerace group.

Education of Parents (New information)

An item on the highest grade of school completed by each parent was added to fetal death certificates in 1968 and was identical to the item added to live birth certificates. As was true in general in comparing information on live birth and fetal death

[#] Ratio not calculated on less than 100 live births.

certificates, reporting was far less complete for fetal deaths; 21 percent of the records for legitimate children did not have the father's education filled in and 18 percent of the total lacked the number of years of school the mother had completed. However, using the records which did have the information entered, it was found that educational levels of the parents who had fetal deaths were about the same as those who had live births. Forty-five percent of the fathers and 53 percent of the mothers had not finished high school, and nearly a third of both fathers and mothers had not gone beyond the ninth grade. Nonwhite parents had received significantly less education than white parents - fathers 3.5 years less and mothers 2.3 years less.

Legitimacy

Almost one-fifth of the fetal deaths were reported as illegitimate. The actual percentage, 19.7, was a little higher than that of 18.8 for live births, but data by race show that this was true only for the whites. A far greater proportion of nonwhite than of white fetal deaths were illegitimate, 32.8 percent in comparison with 5.5 percent, but both figures were lower than in the previous year.

Total-Birth Order (New information)

Fetal deaths in Mississippi had never been classified by number of previous deliveries to the mother before 1968 although there had been items on the certificates concerning this subject. This information was missing from 10 percent of the 1968 records; and even though there is some doubt concerning the accuracy of that which was entered, it was used to determine total-birth order which includes live births plus all fetal deaths regardless of length of gestation. First deliveries made up 24.5 percent of the total. This percentage as well as those for second and third total-birth orders were somewhat lower than the corresponding proportions among live births; the first three orders made up 68 percent of the live birth total but only 52 percent of the fetal death total. The largest number of previous deliveries reported for a mother who had a fetal death in 1968 was 21, which was only one less than the largest number reported for a mother of a live birth.

Fetal death ratios generally increased with total-birth order, ranging from 38.3 per 1,000 live births for those of the first order to 86.7 for those of tenth or higher orders (see Table C4). This correlates with the fact that fetal death ratios rise as the age of the mother increases. It was also noted that for all orders except the eighth and ninth the ratios for whites were higher than those for nonwhites.

Table C4. Fetal death ratios*, by total-birth order and race

Total-Birth Order**	Total	White	Non- white
First	38.3	38.6	37.8
Second	39.7	40.4	38.6
Third	40.6	41.8	39.0
Fourth	53.3	59.2	47.3
Fifth	48.0	50.3	46.4
Sixth	65.5	72.6	62.2
Seventh	68.9	86.4	63.0
Eighth	53.6	43.2	55.8
Ninth	75.3	59.8	77.8
Tenth and over	86.7	125.8	83.8

- * Fetal deaths per 1,000 live births of specified total-birth order and race.
- ** Includes all live births plus all fetal deaths regardless of length of gestation.

Last Prior Delivery (New information)

A new section relating to the last live birth and the last fetal death was added to fetal death certificates in 1968 as it was to live birth certificates in order to obtain data on outcome of the last prior delivery and the interval between it and the current delivery. However, the information was either missing or inadequate to determine the outcome for 16 percent and the interval for 22 percent of the fetal deaths. Also, the accuracy of data which could be used is subject to some doubt.

Twenty-one percent of the fetal deaths (but only 10 percent of the live births) that were from second or later pregnancies had been preceded by a fetal death at the time of the last pregnancy. In addition, it was found that the fetal death ratio among mothers whose last pregnancy also terminated in a fetal death was 103.1 per 1,000 live births in contrast to a ratio of only 40.4 for those whose last pregnancy terminated in a live birth. Both calculations are indicative of the greater likelihood of an unfavorable pregnancy outcome when there is a history of previous fetal deaths.

The median number of months between a fetal death and the last prior delivery was close to the same as that between a live birth and the last prior delivery, 24.5 and 26.0 months respectively. As the figures in Table C5 show, the only marked difference in the median interval prior to a live birth and that prior to a fetal death was for whites whose last delivery was a fetal death; among whites the median interval was 5 months shorter for a fetal death preceded by fetal death than for a live birth preceded by a fetal death. It was also noted that, among both race groups and regardless of whether a live birth or a fetal death occurred, the median length of time since the last delivery was less if the last delivery was a fetal death than if it was a live birth and that the difference was far greater for whites than for nonwhites.

Table C5. Median number of months since last delivery to mothers who had had previous pregnancies, by race, outcome of last delivery, and outcome of delivery in 1968

Race and Outcome	Outcome of Delivery in 1968			
of Last Delivery	Live Birth	Fetal Death		
Total*	26.0	24.5		
White: live birth fetal death	35.1 19.1	35.7 13.8		
Nonwhite: live birth fetal death	22.1 16.9	22.0 15.3		

^{*} Excludes those with outcome of last delivery unknown.

Prenatal Care (New information)

Information on the month of pregnancy prenatal care began and the number of prenatal visits was included on fetal death as well as live birth certificates for the first time in 1968. Reporting of these facts on fetal death certificates was especially poor. For 21 percent of the records it could not be determined whether any care was received.

Sixteen percent of the mothers were reported to have had no prenatal care at all (see Table C6); and, if the facts were known for the large number with no information on the record, the proportion would probably be much higher. In either case, it compares unfavorably with the experience of mothers of live births of whom all but 3 percent received care. It was reported for fetal deaths that 62 percent did receive care, 45 percent began care in the first trimester, only 3.5 percent started care as late as the third trimester, and the average number of visits for those who received care was 4.5 in comparison with 8.4 for mothers of live births. However, since many fetal deaths occurred in the first and second trimesters, there was not as long a period of time in which the mothers could have received care and the figures in the preceding sentence are not really comparable to the same type of data on live births. There was a relatively small difference in the average number of visits for white and nonwhite mothers (4.8 and 4.2 respectively), but the nonwhite mothers could have been expected to have averaged more visits than the white mothers as proportionately more of their reported fetal deaths occurred in the third trimester and fewer in the first trimester.

Table C6. Percentage distribution of live births and fetal deaths by whether mother received prenatal care and race, and average number of visits per mother who received care, by race

Average number of visits per mother who received care	8.4	10.8	5.9	4.5	4.8	4.2	

Length of Gestation and Birth Weight

The collection and tabulation of information on length of gestation and birth weight for fetal deaths is identical to that for live births (see Live Birth section of Synopsis for details). No birth weight was given for 57 percent of the fetal deaths in 1968. Therefore, no data on that topic are presented here although it might be possible to extract some meaningful material from records of fetal deaths of 28 or more weeks gestation since reporting of weight for those occurring in this period was far better than for early fetal deaths. The change in the method of obtaining information on gestation period in 1968 produced better results than before even though the new method was subject to the same deficiencies as were noted in the discussion on live births, including a larger proportion with the number of weeks unknown, 15 percent in comparison with only 4 percent the year before.

Comparative figures on length of gestation as determined in 1967 and from the revised certificate of 1968 are presented in Table C7. The total proportions of early fetal deaths (under 20 completed weeks), those of 20-36 weeks gestation, and at or near term deliveries (37 weeks or more) did not differ greatly from 1967 to 1968, but when the early and term deliveries were separated into more detailed periods it was found that there were changes in opposite directions within these groups. Among early fetal deaths relatively fewer of less than 10 weeks gestation were reported in 1968 and relatively more (especially among whites) with gestations of 10-19 weeks. For term deliveries there was no longer a peak at exactly 40 weeks in 1968 and there were more in the weeks immediately prior to and after the fortieth. This change was quite pronounced for nonwhites; in fact, the drop in the proportion at exactly 40 weeks was so large that it resulted in a decline of some significance in the total percentage of nonwhite fetal deaths at term.

Over 40 Unknown	0.4 4.0	0.5 4.4	0.4 3.7	4.3 14.6	3.7 12.5	4.9 16.6

Sex

A large portion of fetal deaths occur so early in pregnancy that the sex cannot be determined; in 1968, 44 percent of the records did not show sex of the fetus. Those on which the sex was recorded were used to calculate a sex ratio which was 1,496 males per 1,000 females and the highest ever reported for Mississippi. The fetal death sex ratio is always much higher than that for live births (1,051 in 1968). It may be that if the sex could be determined for all fetal deaths a more even distribution would be found, but there is also the possibility that there actually is excessive mortality among the males during pregnancy and labor.

Plurality

In 1968, 3.6 percent of the fetal deaths were from plural deliveries, and the rate of occurrence was greater among nonwhites than among whites, 4.8 and 2.3 percent respectively. As usual, the frequency among fetal deaths was higher than that among live births (only 2.5 percent).

Further analysis of plurality among both live births and fetal deaths revealed that I out of every 79 pregnancies resulted in a set of either twins or triplets in 1968. The ratio for whites was only I in every 100, but that for nonwhites was I in every 65. Twin sets numbered 595 and there were 7 sets of triplets. All the children were born alive in 89.5 percent of the plural deliveries, 7 percent had both live and dead members, and all were born dead in 3.5 percent of the cases. When fetal mortality from single deliveries was compared with the information on the plural sets it was found that 6.9 percent of the fetuses from these plural sets was born dead in contrast to only 4.8 percent of those from single births and that the difference was more pronounced among nonwhites than among whites.

Cause of Fetal Death, Complications of Pregnancy and Labor, Birth Injuries, and Congenital Malformations

Although fetal death certificates contained a section for cause prior to 1968, the information, if any, entered in this section was of too poor quality to classify. This was also true of the records filed in 1968. However, an attempt was made to use the data entered in the new sections on complications of pregnancy and labor, birth injuries, and congenital malformations which were added when the certificate was revised in 1968. It was planned that a comparative study would be made comparing the occurrence of these events when the outcome was a live birth and when it was a fetal death, but the recorded information was so poor that it was not possible to code it. Of particular concern was the fact that entries in the cause section and the new sections were frequently inconsistent and even conflicting.

がなった。

Walter Street

DEATHS (See Tables 5-8, 12-16)

Trend

The death total of 23,986 Mississippi residents for 1968 was the largest on record since 1937 and represents an increase of 1,377 over the previous year. An increase was also registered in the death rate which went up from 9.6 to 10.2 per 1,000 population. The figure for 1968 was the same as the rate for 1963 but higher than those for any of the years in between. However, as mentioned in the section on live births, population estimates for the latter part of a decade are especially subject to inaccuracies because of the length of time since the last decennial census, and rates based on them would be affected accordingly.

Race

Counts for both whites and nonwhites rose in 1968; in fact, the death toll of 13,468 for whites was the highest ever recorded in this state. The rates for the two groups were 9.3 (whites) and 11.7 (nonwhites), and the difference between them was greater than in 1967 because that for nonwhites went up more than that for whites.

County and Urban-Rural Variation

Death rates varied considerably by county. For the white population the range was from 5.1 in Jackson and Tunica Counties to a high in Wilkinson County of 15.6, which was over three times the lowest rate. Rates for nonwhites ranged from 6.6 in Rankin County to 18.0 in Greene County. The fact that many rural residents go into towns and cities for health care is evident from death figures, as it was from birth data; although only 40 percent of the deaths occurred among urban residents, 62 percent occurred in urban locations.

Month

Data in Table Dl show that far more deaths occurred in January than in any other month and that the daily average was also considerably higher. The smallest number and lowest daily average were recorded in July, but figures for several other months were

nearly as low. The seasonal picture revealed is one of excess mortality during the part of the year when the coldest weather occurs.

Month	Deaths	Average per Day	Month	Deaths	Average per Day
<u>Total</u>	23,986	66			
January	2,727	88	July	1,822	59
February	1,998	69	August	1,879	61

May	1,875	60	November	1,941	65
June	1,933	64	December	2,252	73

Table D1. Deaths and average per day, by month

Age at Death

There has been an upward, though not unbroken, trend in the median age at death in recent years. The median age in 1968 was 68.9 which is exactly two years more than it was in 1961; the change between 1967 and 1968 alone amounted to 0.8 of a year. Medians of 70.7 and 66.6 years were calculated for the whites and nonwhites respectively. In both groups the trend has been upward and the gap between the two has narrowed. As may be seen in Table D2, the number of deaths among persons 75-84 years of age was larger than the number for any other ten-year age group with the count for persons 65-74 years old not far behind. The smallest total for a ten-year age span was that for children 5-14 years old. Differences between the age distributions of whites and nonwhites were minor except among the very young and the very old. Of special significance is the fact that only 3.8 percent of the whites who died were under the age of one but the proportion for the nonwhites was 10.4 percent.

Leading Causes of Death

Table D3 lists the ten leading causes of death and shows that 79 percent of the total deaths were attributed to this group of causes. Relatively more of the whites than of the nonwhites died from these causes, but this was principally due to the differences in the proportions assigned to the two top-ranking causes. Heart diseases and malignant neoplasms together accounted for 53 percent of the deaths among the white population but only 39 percent of those among nonwhites. The first eight causes are the same ones which were listed in the previous year, although the order of those in the fifth through the eighth places varied. Homicide, in tenth place in 1968, had appeared on the list in two other years in the 1960's, but the combination of respiratory diseases which ranked ninth is a new grouping being used since the revised system of classifying causes of death went into effect in 1968. In comparing the ranking of certain causes in 1968 with that for prior years, it should be realized that some of the variation probably resulted from the change in the classification system; for example, only about 89 percent of the deaths which would have been assigned to arteriosclerosis in the old system would have been placed in this category under the new system.

Table D3. Deaths and percent of total deaths from ten leading causes, by cause and race

Leading Causes by Age

Listed in Table D4 are the five leading causes of death for each age group except infants (infant mortality is discussed in another section). Although each of these lists was different from any of the others, malignant neoplasms and accidents appeared on every one and heart diseases on all except that for children 1-4 years old. However, the number of deaths of children and young adults under the age of 25 that were due to malignant neoplasms and heart diseases was relatively insignificant. The leading cause of death for ages 1-44 was accidents and for ages 45 and over, heart diseases. Of special note is the fact that among persons 15-24 years of age the two leading causes of death were external causes (accidents and homicide) rather than diseases and were responsible for 64 percent of the total in that group.

Table D4. Deaths and percent of total deaths from five leading causes, by age and cause

Ill-defined and Unknown Causes

A substantial number of the death certificates filed in Mississippi do not have a satisfactory statement of cause of death. In 1968, there were 1,872 deaths in the state for which the cause could only be classified in a category called "symptoms and ill-defined conditions". This group made up 7.9 percent of the total with far more of the records for nonwhites (13.2) thus classified than for whites (3.7 percent). If the 279 certificates for infants whose stated cause of death was immaturity with no additional information were also included as ill-defined, the overall total would be 2,151 and the percentage 9.1. However, considering only those deaths in the category which is actually labeled as ill-defined, review of this information by county of occurrence of death revealed that 20 percent or more of the certificates lacked a satisfactory statement of cause in five counties - Amite, Benton, Issaquena, Noxubee (a high of 31 percent), and Yazoo. For six other counties (DeSoto, Hancock, Holmes, Madison, Marion, and Tunica) the rate was 15-19 percent. If the cause of this large group of deaths could be determined and tabulated, the order of the leading causes and even the causes themselves might change.

Specific Causes

Heart disease, the leading cause of death in Mississippi as well as in the nation, has been the leading cause in this state in every year from 1925 to the present with the exception of 1929. Accounting for 33 percent of the deaths among residents in 1968, the death toll of 7,969 and the death rate of 339.0 per 100,000 population were the highest ever recorded in Mississippi. Although the rate of 346.4 for the white population was higher than that of 327.1 for nonwhites, the difference between the two was not excessively large. Data in Table D5 show that ischemic heart disease caused most of the deaths due to heart disease; the principal category within this group was acute myocardial infarction which alone accounted for 4,039 deaths.

Cause and International Classification Number	Total	White	Non- white
Diseases of heart (390-398, 402, 404-429)	7,969	5,024	2,945
Active rheumatic fever and chronic rheumatic heart disease (390-398)	98	61	37
Hypertensive heart disease with or without renal disease (402, 404)	296	91	205
Ischemic heart disease (410-414)	6,818	4,496	2,322
Chronic disease of endocardium and other myo- cardial insufficiency (424, 428)	166	87	79
Other forms of heart disease (420-423, 425-427,	591	289	302

Table D5. Deaths from diseases of heart, by type and race

Malignant neoplasms again ranked second on the list of leading causes, having moved up from third to second place in the previous year. As was true for the leading cause, heart disease, the number of deaths (3,267) and the death rate of 139.0 per 100,000 population were the highest on record in Mississippi; however, cancer was responsible for less than half as many deaths as heart disease. Another similarity between these two causes is that the death rate for cancer was higher for whites than for nonwhites but not extremely so. In the section on leading causes of death by age it was noted that cancer

was one of the five leading causes for every age group except infants. Despite this, comparatively few deaths from malignant neoplasms occurred among young persons; in fact, only 8 percent of the total occurred among persons under the age of 45. Study of the organs or systems of the body where the primary neoplasm was located revealed that the three principal sites were the digestive organs and peritoneum (920 deaths), the respiratory system (634 deaths), and the genital organs (501 deaths).

Cerebrovascular disease was the third leading cause of death with a total count (3,115) and a death rate (132.5) that were not much below those for malignant neoplasms. Figures by race show that this disease is one that was especially serious among the non-white population as it ranked second on their list of leading causes and their rate was 47 percent higher than the rate for whites. No trend, either upward or downward, in the mortality from this disease has been noted in over ten years.

Chronic respiratory diseases have been the object of much concern during the 1960's and even earlier because of the rise in both illnesses and deaths due to some of these conditions. In Table D6 the diseases responsible for the largest numbers of deaths are listed with the death toll from each in 1968 and 5, 10, and 15 years earlier. Figures for 20 or more years earlier are not shown because of a major difference in the classification system for causes of death. Although the system was revised again in 1958 and 1968, the changes in 1958 were very minor and only one of the causes in this table was significantly affected by the revision in 1968. For this one cause, asthma, adjusted data for the years prior to 1968 are also given in order to provide a set of comparable figures.

Mortality from tuberculosis of the respiratory system declined considerably in the last 15 years. In contrast, there was a sharp rise in the death counts for malignant neoplasms of the respiratory system and emphysema. In 1968 cancer of the respiratory system caused more deaths than the total of all of the other diseases listed in the table. The number of deaths attributed to cancer of this site increased by 184 percent since 1953, and those from cancer of just the trachea, bronchus, and lung tripled in that time. The upswing in fatal cases of emphysema was even more dramatic with an increase from 12 to 213 deaths in the past 15 years. For chronic and unqualified bronchitis and for asthma no trends in either direction were maintained, although the general level of mortality from bronchitis was higher in the 1960's than in the 1950's.

Table D6. Deaths from major chronic respiratory diseases, 1953, 1958, 1963, 1968

Cause and International Classification Number	1953	1958	1963	1968
Tuberculosis of respiratory system (010-012)	293	154	106	78

Malignant neoplasms of trachea, bronchus, and lung				
(162)	200	279	443	602
Chronic and unqualified bronchitis (490, 491)	28	31	49	38
Emphysema (492)	12	61	152	213
Asthma (493)	62	58	45	52
(Adjusted figures*)	(43)	(40)	(31)	L

^{*} Adjusted according to a comparability ratio prepared by the National Center for Health Statistics in order to compensate for a break in comparability caused by revision of the cause-of-death classification system in 1968.

Influenza and pneumonia moved up to fifth place on the list of leading causes in 1968 after being in sixth place for the previous 19 years during which the ranking of leading causes was comparable. The total of 825 deaths in 1968 was 168 more than occurred in 1967 and the highest number since 1963. However, 1968 was not a year of extremely high mortality as in seven of the last twenty years the death toll from this causes was higher than it was in 1968. Included in the figure for 1968 were 729 deaths from pneumonia, 59 from influenza with pneumonia, and 37 from influenza without mention of pneumonia. Data by race showed that, as usual, the rate for nonwhites was substantially larger than that for whites, 45.6 in comparison with 28.5 per 100,000 population.

機能は大き

Accidents caused the death of 1,723 Mississippians in 1968. This toll and the death rate of 73.3 per 100,000 population have been surpassed in only two other years, 1966 and 1967 when the counts were 1,872 and 1,890 respectively. On the list of leading causes of death, accidents ranked fourth and was the leading cause for persons 1-44 years old. Over half of the deaths among persons 5-24 years of age were due to accidents, and this cause was responsible for several times as many deaths in these age groups as the second-ranking causes. November was the peak month of occurrence with December ranking second.

The five principal types of fatal accidents among Mississippi residents are shown in Table D7 and are the same ones which have been listed for a number of years. Together they accounted for nearly 80 percent of the total and the top-ranking type, motor vehicle accidents, accounted for 48 percent. Although the 821 deaths caused by motor vehicle accidents was the third highest count on record for Mississippians, this number was 110 less than the peak number reported the year before, and the decline which occurred in 1968 followed five successive years in which the total for each year surpassed all previous years.

Table D7. Deaths and percent of total accidental deaths from five leading causes of accidental death, by cause and race

		Number		Percent			
Type of Accident and International Classification Number	Total	White	Non- white	Total	White	Non- white	
Total of five leading causes	1,370	806	<u>564</u>	79.5	80.7	77.9	
 Motor vehicle (810-823) Fires and flames (890-899) Falls (880-887) 	821 208 157	542 68 115	279 140 42	47.6 12.1 9.1	54.2 6.8 11.5	38.5 19.3 5.8	
4. Drowning, except in water transport (910) 5. Firearm (922)	111 73	42 39	69 34	6.4 4.2	4.2 3.9	9.5 4.7	

A special compilation of data on accidental deaths that occurred in Mississippi showed that for ages 5-64 the leading cause of accidental death was motor vehicle accidents. For infants under one year of age it was mechanical suffocation; for ages 1-4 it was fires and flames; and for persons 65 and over it was falls.

Suicide and homicide were the causes of death of 171 and 256 Mississippians in 1968. Suicide was not on the list of ten leading causes but did rank in tenth place among the white population. Homicide was of even greater significance as indicated by the fact that it ranked in tenth place in the total population, in second place among young

persons 15-24 years of age, in fourth place among those 25-34 years old, in eighth place among nonwhites, and in eighth place among males. A preponderance of males was noted for both suicides and homicides, but there was a sharp contrast in the occurrence of these events by race. The suicide rate among whites was nearly four times as great as that among nonwhites, but the homicide rate was over five times greater for nonwhites than for whites. An overwhelming majority of both suicides and homicides were accomplished by firearms and explosives - 82 percent of the suicides and 73 percent of the homicides.

Injury undetermined whether accidentally or purposely inflicted is the title of a new category in the cause-of-death classification system which went into effect in 1968. Formerly all deaths not due to natural causes (except those resulting from war operations) had to be classified as either accident, suicide, or homicide. If the certifier could not or would not make a decision, the death certificate was left as the certifier had prepared it but one of the three categories listed above was assigned for tabulating purposes according to certain prescribed rules. In most instances these deaths were classified as accidents. The new category, which was reflected in the design of the revised death certificate, was intended to eliminate such automatic decisions and also incorrect choices by certifiers who made assignments without substantiating evidence just because a decision was expected of them. The number of deaths assigned to this category in 1968 was 51, and 22 resulted from injuries by firearms and explosives. Counts by race were 24 white persons and 27 nonwhites; approximately half were 25-44 years of age.

Maternal deaths are defined as those resulting from deliveries and complications of pregnancy, childbirth, and the puerperium. In 1968 the number in this category was 21 and the death rate was 4.6 per 10,000 live births. Both of these figures were record lows for Mississippi. From the data in Table D8 it may be seen that mothers 15-24 years of age had the lowest maternal death rate and that there was a marked disparity between the rates for whites and nonwhites, 1.3 and 7.8 respectively. Eight deaths were attributed to toxemia, 5 to hemorrhage, 2 to sepsis, and 6 to various other causes.

	Number				Rate*	
Age	Total	White	Non- white	Total	White	Non- white
<u>Total</u>	21	3	<u>18</u>	4.6	1.3	7.8
10-14	1	0	1	32.2	_	34.8
15-24	8	0	8	2.9	-	5.8
25-34	10	2	8	6.9	2.5	12.3
35-44	2	1	1	5.5	7.7	4.3
45-54	1 0	1 0	0	_	_	_

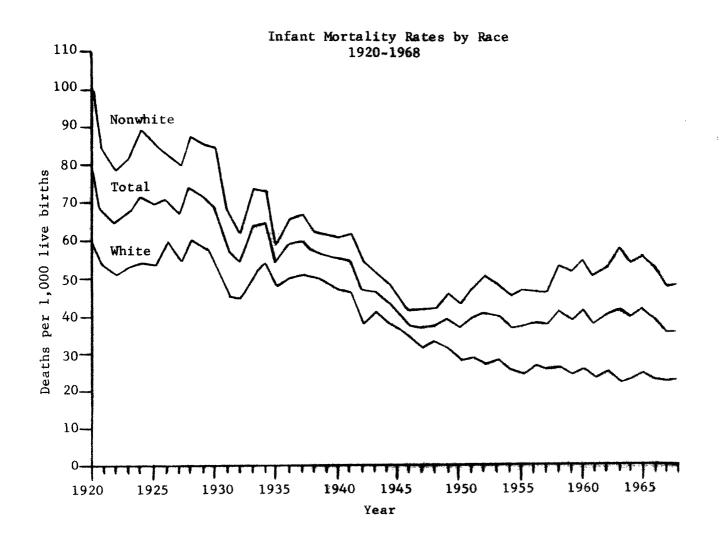

Table D8. Maternal deaths and maternal death rates, by age and race

Infant Mortality

The number of infant deaths declined slightly in 1968 to reach a new record low

^{*} Deaths per 10,000 live births to mothers in specific age-race group.

of 1,613. No change occurred in the death rate which remained at 35.3 per 1,000 live births; this was also the lowest on record, however. Despite the fact that the infant mortality rate reached a new low in 1967 which was maintained in 1968, the problem is still serious. The death rate of 35.3 was not much below the rate of 36.6 which was recorded 21 years earlier in 1947. As the accompanying graph shows, 1947 was the last year of a long-term downward trend in the total infant mortality rate. In the intervening years only slight progress was made in reducing the rate for white infants and for nonwhite infants the trend was upward with indication of a reversal of this trend just in the last few years. In addition, Mississippi's rate was the highest in the nation. It was 31 percent above that for South Carolina which had the second highest rate and 62 percent above that for the nation as a whole. The race-specific rates for Mississippi were also excessive - 18 percent above the national level for whites and 39 percent for non-whites.

Data relating to infant deaths by age and race are presented in Table D9. More deaths occurred in the first of life (35 percent of the total) than in either the next 27 days or the other eleven months of infancy. Total neonatal deaths (those in the first 28 days of life) amounted to 69 percent of those in the first year leaving only 31 percent in the postneonatal period. The infant death rate of 47.8 for nonwhites was more than

1.00

· ·

double the rate of 22.7 for whites. Although rates for nonwhites were higher than those for whites in each age group, the discrepancy was greatest for children 28 days to one year of age. The excessive mortality of nonwhite babies in this age group is a significant factor in the state's extremely high infant death rate. However, Mississippi's neonatal death rate was also the highest in the country and substantially higher than that for any other state.

		Number		Rate*			
Age	Total	White	Non- white	Total	White	Non- white	
Total	1,613	517	1,096	35.3	22.7	47.8	
Under one day One to 28 days	565 551	225 199	340 352	12.4 12.0	9.9 8.7	14.8 15.4	
28 days to one year	497	93	404	10.9	4.1	17.6	

Table D9. Infant deaths and infant death rates, by age and race

In previous years a table which listed the leading causes of infant death in rank order was presented in this section on infant mortality. Since no system of ranking infant causes or even grouping them has been standardized yet for the new cause-of-death classification which went into use in 1968, Table D10 presents some causes and cause groups which appeared to be significant. The category on the table with the largest number of deaths, 323, is anoxic and hypoxic conditions not elsewhere classifiable and has as its three major components hyaline membrane disease (92 deaths), respiratory distress syndrome (71 deaths), and unspecified asphyxia of the newborn (143 deaths). A cause group only partially provided for in the previous classification system is that for infant deaths resulting from complications of pregnancy and child-birth. Deaths assigned to this group totaled 114 with 29 resulting from complications due to a multiple pregnancy and 25 from premature separation of the placenta. A breakdown of the 77 accidental deaths showed that 28 were due to mechanical suffocation and 23 were caused by inhalation or ingestion of food or other objects.

Analysis of age at death and race of the infants who died from the causes listed in Table D10 revealed pronounced contrasts. Death rates from diarrheal disease, influenza and pneumonia, and accidents were respectively 27, 5, and 2 times higher for nonwhites than for whites, but the rate for congenital anomalies was twice as high among whites as among nonwhites. Regarding age at death, all but a very few of the deaths from anoxic and hypoxic conditions and from complications of pregnancy and child-birth occurred among babies less than one week old, 69 percent of the deaths caused by congenital anomalies occurred in the neonatal period, and two-thirds or more of the deaths attributed to diarrheal disease, influenza and pneumonia, and accidents were in the postneonatal period.

^{*} Deaths per 1,000 live births.

elsewhere classifiable (776)	323	163	160	7.1	7.1	7.0
Immaturity, unqualified (777)	283	76	207	6.2	3.3	9.0
Accidents (800-949)	77	26	51	1.7	1.1	2.2

^{*} Deaths per 1,000 live births.

If immaturity is mentioned on a death certificate with some other condition(s), it is not classified as the underlying cause because of the vagueness of the term, but some certificates show no other condition except immaturity. In 1968 this total was 283 which is the second largest in Table D10. In addition, there were 233 other deaths with no definite statement of cause which made a total of 516 in the "ill-defined" categories. This was 32 percent of the total infant deaths; 39 percent of those among nonwhites and 41 percent of those among infants under one day of age were thus classified. The magnitude of these figures indicates a major difficulty in the study of the problem of infant mortality.

MARRIAGES (See Tables 9, 17)

· 李生

Trend

The year 1968 was the ninth in succession in which the number of marriages went up. Weddings occurring in that year numbered 25,355, an increase of nearly eight percent over the figure for 1967, and the size of the increase was much larger than that in any other year of this period of upward trend. The rise in marriages is no doubt due to a shift in the age distribution of the population as the unusually large number of children born in the years immediately after World War II reach marriageable age and also to overall growth of the state's population. For both whites and nonwhites the trend has been upward, though not unbroken, with the latest counts 17,142 and 8,213 respectively.

Month

As expected, marriages in June far outnumbered those in any other month (see Table E1). August ranked second in number and daily average with December in third place. During the 1960's the order in which these two months ranked usually depended on which one had five Saturdays, as more marriages occur on Saturday than any other day of the week. The National Center for Health Statistics reported that, in 1968, 34 percent of the

marriages in Mississippi occurred on Saturday. This concentration and the fact that there can be either four or five Saturdays in any month result in year-to-year variations in the number of marriages occurring in any certain month.

Month	Marriages	Average per Day	Month	Marriages	Average per Day

May	1,983	64	November	2,032	68
June	3,263	109	December	2,469	80

Table El. Marriages and average per day, by month

Officiant

The ceremony was performed by a minister at 72 percent of the marriages. Justices of the peace officiated at nearly all the rest with only a few conducted by mayors, judges, members of boards of supervisors, and other persons.

Age of Bride and Groom

Information in Table E2 shows that 10,444 of the brides married in Mississippi in 1968 were teenagers (or subteenage). They comprised 41 percent of the total, and 4,589 or 18 percent were less than 18 years of age. One bride only 12 years old, 13 who were 13 years old, and 89 who were 14 were included in this group. Teenage grooms numbered 4,697 which was 18 percent of the total. The youngest were only 14 years old and 783 were under age 18. Old age as well as extreme youth was represented among those getting married, however, with 31 brides and 145 grooms in the group 75 years of age or older. The oldest ages were 97 for grooms and 85 for brides. Differences in age distribution by race were not large, but for both brides and grooms the proportions of whites under age 25 were higher than the proportions of nonwhites of that age.

As may be seen from the figures in Table E3 which shows median ages at marriage, brides were younger than grooms (as is to be expected) and white brides and grooms were younger than nonwhites of the same sex. Information is also given for brides and grooms marrying for the first time. These brides and grooms had lower median ages, but the same relationships between the races and the sexes were noted as for all marriages.

Marriage Order and Previous Marital Status

Data presented in Table E4 show that 73 percent of the brides and 73 percent of the grooms who married in 1968 were married for the first time. However, the proportion of weddings in which both bride and groom were married for the first time was somewhat smaller, 66 percent. Most of those who had been married before had only one previous marriage, but 1,622 brides and exactly the same number of grooms undertook a marriage of third or higher order and one bride began her eighth marriage. Far more of both brides and grooms were divorced than were widowed.

Table E4. Brides and grooms and percentage distribution, by marriage order and previous marital status

previous marriages

or divorced

Unknown whether any

Nonresident Brides

Fifteen percent of the brides married in Mississippi in 1968 were not residents of the state, and in 12 percent of the marriages neither the bride nor the groom was a state resident. Although the 3,738 nonresident brides came from 44 of the other 49 states, the District of Columbia, and also from foreign countries, 79 percent were from the neighboring states of Alabama, Arkansas, Louisiana, and Tennessee. DeSoto County, just south of Memphis, Tennessee, issued 20 percent of the licenses to nonresident brides, and all Mississippi border counties together accounted for 76 percent.

Out-of-State Use of Mississippi Licenses

Some marriage licenses issued in Mississippi are used for weddings performed in other states. Such marriages are not included in the annual tabulations for this state because they did not occur here and are of questionable legality. Special counts of these records have been made during a twelve-year period, and the total of 71 in 1968 is the smallest recorded during that time. The bride and/or groom resided in the state

^{*} Includes those whose last marriage was annulled.

^{**} Less than 0.06 percent.

of occurrence in 72 percent of these cases, and in all except one of the remaining cases the bride and/or groom resided in Mississippi. States which border on Mississippi were the site of all but 8 of the weddings with 37 occurring in Louisiana. It was also noted that two-thirds of the licenses were obtained in Mississippi counties adjacent to the state where the wedding took place.

DIVORCES (See Tables 9, 10, 17)

Trend

In 1968 the number of divorces in Mississippi was the second largest on record. The total of 7,020 was exceeded only in 1946 when an extremely high peak was reached following World War II. Counts for both whites and nonwhites went up in 1968, with that for the whites also the second largest on record and almost 1,000 more than occurred only three years earlier.

Cause and Complainant

The most frequently given reason for divorce was cruel and inhuman treatment which was listed for 62 percent of the cases. Desertion ranked second with 29 percent and was the stated cause of more than half of those among nonwhite couples. Together these two causes accounted for 91 percent of the divorces granted in this state in 1968. The wife was the complainant in 71 percent of the cases involving white persons, but in only 53 percent of those among nonwhites.

Minor Children

A large proportion of the couples who were granted divorces stated that they had no minor children - 42 percent of the white and 50 percent of the nonwhite couples. Those who did have minor children averaged 2.2 per family with a total of 8,382 children reported. There were 274 families with five or more children and 5 of these had between ten and thirteen minor children.

Duration of Marriage

The length of time married before obtaining a divorce covered a broad range - from less than one year to 62 years. Eight percent of the divorces occurring in 1968 came after less than one year of marriage and 42 percent were granted during the first five years. However, approximately one-sixth of the couples had been married twenty years or longer and 20 had been married for fifty or more years. There was a substantial disparity between the length of time reported for whites and nonwhites. The median duration for whites was 5.1 years with 49 percent in the first five years, but for nonwhites the median was 12.4 years with only 23 percent in the first five years.

Additional Information Needed

Mississippi's statistical record of divorce is a form which provides only limited information because of the omission of a number of pertinent items which many other states collect and also because of the lack of clarity regarding some of the items which are on the form. No data at all are available concerning place of marriage, place of residence of the couple at time of separation, their ages at marriage and at divorce, previous marriages, and socio-economic factors. Information which is presently tabulated on minor children, cause of divorce, and complainant probably is erroneous because of lack of definitions and instructions regarding how such facts should be entered on the form and also because of the poor arrangement of the form. These deficiencies seriously hamper meaningful study of the divorce problem on a state level as well as on a national level. Since Mississippi's record does not contain even what is considered minimum information, this state is not eligible to become part of the National Divorce Registration Area. Revision of the statistical record of divorce would be of great help in providing material for analysis of this serious social problem.

^{*} Total number of marriages for 1926 and total number of divorces for 1926 and 1927 furnished by U.S. Bureau of Census; distribution by race not available.

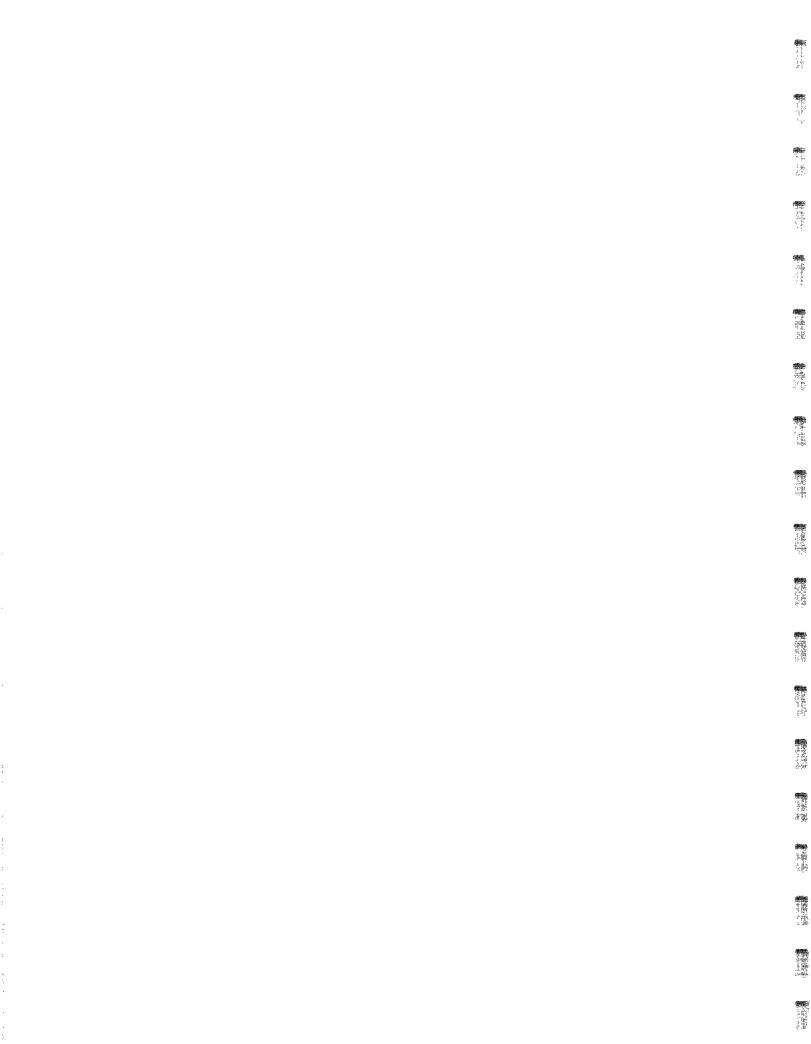

[#] Includes some records on which the race of the couple was not stated.

BIRTHS, FETAL DEATHS, DEATHS

THE COUNTIES AND THE STATE OF MISSISSIPPI, 1968

Footnote for Tables on Pages 61-143

* Total births and deaths per 1,000 population. Fetal deaths, deaths under 1 year, deaths under 28 days, and deaths from certain causes of mortality in early infancy per 1,000 live births. Maternal deaths per 10,000 live births. Deaths from other specific causes per 100,000 population.
